

Why be so Critical?

Nineteenth Century Mathematics and the Origins of Analysis

Janet Heine Barnett*

December 22, 2016

One striking feature of nineteenth century mathematics, as contrasted with that of previous eras, is the higher degree of rigor and precision demanded by its practitioners. This tendency was especially noticeable in *analysis*, a field of mathematics that essentially began with the “invention” of calculus by Leibniz and Newton in the mid-17th century. Unlike the calculus studied in an undergraduate course today, however, the calculus of Newton, Leibniz and their immediate followers focused entirely on the study of geometric *curves*, using algebra (or ‘analysis’) as an aid in their work. This situation changed dramatically in the 18th century when the focus of calculus shifted instead to the study of *functions*, a change due largely to influence of the Swiss mathematician and physicist Leonhard Euler (1707–1783). In the hands of Euler and his contemporaries, functions became a powerful problem solving and modelling tool in physics, astronomy, related mathematical fields such as differential equations and the calculus of variations. Why then, after nearly 200 years of success in the development and application of calculus techniques, did 19th-century mathematicians feel the need to bring a more critical perspective to the study of calculus? This project explores this question through selected excerpts from the writings of the 19th century mathematicians who led the initiative to raise the level of rigor in the field of analysis.

1 The Problem with Analysis: Bolzano, Cauchy and Dedekind

To begin to get a feel for what mathematicians felt was wrong with the state of analysis at the start of the 19th century, we will read excerpts from three well-known analysts of the time: Bernard Bolzano (1781–1848), Augustin Cauchy (1789–1857) and Richard Dedekind (1831–1916). In these excerpts, these mathematicians expressed their concerns about the relation of calculus (analysis) to geometry, and also about the status of calculus (analysis) in general. As you read what they each had to say, consider how their concerns seem to be the same or different. The project questions that follow these excerpts will then ask you about these comparisons, and also direct your attention towards certain specific aspects about the excerpts.

Bernard Bolzano, Rein Analytischer Beweis des Lehrsatzes...Gleichung liege, 1817

There are two propositions in the theory of equations of which it could still be said, until recently, that a completely correct proof was unknown. One is the proposition: *that between any two values of the unknown quantity which give results of opposite signs there must always lie at least one real root of the equation.* The other is: *that every algebraic rational integral function of one variable quantity can be divided into real factors of first or second degree.* After several unsuccessful attempts by d'Alembert, Euler, de Foncenex, Lagrange, Laplace, Klügel, and others at proving the latter proposition Gauss finally supplied, last year, two proofs which leave very little to be desired. Indeed, this outstanding scholar had already presented us with a proof of this proposition in 1799, but it had, as he admitted, the defect that it proved a purely analytic truth on the basis of a geometrical consideration. But his two most recent proofs are quite free of this defect; the trigonometric functions which occur in them can, and must, be understood in a purely analytic sense.

The other proposition mentioned above is not one which so far has concerned scholars to any great extent. Nevertheless, we do find mathematicians of great repute concerned with the proposition, and already different kinds of proof have been attempted. To be convinced of this one need only compare the various treatments of the proposition which have been given by, for example, Kästner, Clairaut, Lacroix, Metternich, Klügel, Lagrange, Rösling, and several others.

However, a more careful examination very soon shows that none of these proofs can be viewed as adequate.

The most common kind of proof depends on a truth borrowed from *geometry*, namely, *that every continuous line of simple curvature of which the ordinates are first positive and then negative (or conversely) must necessarily intersect the x-axis somewhere at a point that lies in between those ordinates.* There is certainly no questions concerning the correctness, nor the indeed the obviousness, of this geometrical proposition. But it is clear that it is an intolerable offense against correct method to derive truths of pure (or general) mathematics (i.e., arithmetic, algebra, analysis) from considerations which belong to a merely applied (or special) part, namely, *geometry*. [...]

Augustin Cauchy, Cours d'Analyse, 1821

I have sought to give to the methods [in this text] all the rigour which is demanded in geometry, in such a way as never to refer to reasons drawn from the generality of algebra.[Reasons drawn from the generality of algebra] tend to cause an indefinite validity to be attributed to the algebraic formulae, while in reality the majority of these formulae hold only under certain conditions, and for certain values of the variables which they contain. By determining these consideration and values, and by fixing precisely the meaning of the notations I shall make use of, I shall dispel all uncertainty.

Augustin Cauchy, Leçons sur le calcul infinitésimal, 1823

My principal aim has been to reconcile rigor . . . with the simplicity which results from the direct consideration of infinitesimals. I therefore rejected divergent series expansions, and deferred Taylor's formula to the integral calculus [because its remainder is given by an integral formula]. I am aware that [Lagrange] used Taylor's formula as the basis of this theory of the derivative. But . . . most geometers are now dubious about the use of divergent series; moreover in some cases when the Taylor series converges, its sum differs from the given function.

Richard Dedekind, Stetigkeit und irrationale Zahlen, 1872

My attention was first directed toward the considerations which form the subject of this pamphlet in the autumn of 1858. As professor in the Polytechnic School in Zürich I found myself for the first time obliged to lecture upon the elements of the differential calculus and felt more keenly than ever before the lack of a really scientific foundation for arithmetic. In discussing the notion of the approach of a variable magnitude to a fixed limiting value, and especially in proving the theorem that every magnitude which grows continually but not beyond all limits, must certainly approach a limiting value, I had recourse to geometric evidences. Even now such resort to geometric intuition in a first presentation of the differential calculus, I regard as exceedingly useful, from the didactic standpoint, and indeed indispensable, if one does not wish to lose too much time. But that this form of introduction into the differential calculus can make no claim to being scientific, no one will deny. For myself this feeling of dissatisfaction was so overpowering that I made the fixed resolve to keep meditating on the question until I should find a purely arithmetic and perfectly rigorous foundation for the principles of infinitesimal analysis.

Question 1

In what way do the concerns of these three mathematicians about the relation of calculus (analysis) to geometry, and about the status of calculus (analysis) in general, seem to be the same/different?

Question 2

This question looks back at some of the mathematical details mentioned by Bolzano, Dedekind and Cauchy.

(a) Note that:

- Bolzano discusses two specific theorems — identify or list these theorems here:

- Dedekind discusses one specific theorem — identify or list that theorem here:

- Cauchy makes reference to the Taylor formula and related results — look back to see what he has to say, and briefly describe his concerns.

(b) Which of the results in part (a) are familiar to you?

For each that is, try to state it in “modern” terms, or give its “modern name”.

(c) Which of the results in part (a), if any, do you believe to be true (and why)?

2 Niels Abel: *Can you keep from laughing, friends?*

In this section, we will examine an excerpt from a letter written by young Norwegian mathematician Niels Abel (1802–1829) to his high school teacher, Bernt Michael Holmboe, on January 26, 1826. Abel is often remembered for his celebrated impossibility proof in the theory of equations in which he proved that a ‘quintic formula’ for the general fifth degree polynomial equation does not exist — a proof that marked an important step in the mathematical quest for algebraic solutions to polynomial equations which began with the development of Babylonian procedures for solving quadratic equations in 1700 BCE. Abel is equally well known for his work in analysis, and especially the theory of elliptic functions. In his letter to Holmboe, written during a study-abroad trip to Paris, Abel describes some of his concerns about the state of analysis in general, and particularly about the use of infinite series. The **letter itself (in English translation) appears on pages 8– 9** of this project; after reading it, complete your responses to questions 3 – 6 below.

Question 3

Find at least two references in Abel’s letter to series as an important concept or issue in mathematics.

To what degree do the concerns that Cauchy expresses about series agree with Abel’s view of series?

Question 4

What is it that Abel thought was “exceedingly surprising” about the “current” state of mathematics? Be specific here!

Do you agree with his reaction to this state of affairs? Explain.

Question 5

Towards the end of this excerpt, Abel remarked that a series of the following form can be convergent for ‘ x less than 1’, but divergent for $x = 1$:

$$\phi(x) = a_0 + a_1x + a_2x^2 + \dots$$

- (a) Provide an example in which this occurs, specifying both the series (by giving values for the coefficients a_0, a_1, \dots) and the function $\phi(x)$ to which that series converges for ‘ x less than 1’. (Note: You don’t really need to work too hard to do this.)

- (b) Notice that Abel went on to speculate that an even worse situation might occur. Namely, he proposed the possibility that a series $\phi(x) = a_0 + a_1x + a_2x^2 + \dots$ might be convergent for ‘ x less than 1’ *and* convergent for $x = 1$, but in such a way that $\lim_{x \rightarrow 1} \phi(x)$ is not equal to $\phi(1)$.

What mathematical concept is involved here? That is, if such a function ϕ does in fact exist, what function property is ϕ lacking?

Question 6

Consider the following series discussed by Abel at the end of this extract:

$$\frac{x}{2} = \sin x - \frac{1}{2} \sin 2x + \frac{1}{3} \sin 3x - \text{etc.}$$

- (a) Describe how this series is different from a power series.
- (b) Now complete Abel's arguments concerning the numerical aspects of this series by determining what is absurd about this formula for $x = \pi$.
- (c) Next complete Abel's comments about the differential aspects of this series by differentiating the formula term-by-term in order to show what can go wrong when one "applies operations to infinite series as if they were finite". [Be sure to say what is wrong with the differentiation results!]

Heinrik Abel, Berlin Letter to Holmboe, 1826

Since my arrival in Berlin I have also occupied myself with the solution of the following general problem: *To find all the equations which can be solved algebraically.* I have not yet solved it, but as nearly as I can judge, I am close. When the degree of the equation is prime, it is not too difficult, but when this number is composite, the devil mixes in. I have found a large number of solvable equations, in addition to those already known. When I have finished the paper which I hope to write, I flatter myself that it will be good. It will be general, and one will find there a method, which seems to be the most essential point.

Another problem with which I have occupied myself a lot is the summation of the series

$$\cos mx + m \cos(m-2)x + \frac{m(m-1)}{2} \cos(m-4)x + \dots$$

When m is a positive integer, the sum of this series as you know, is $(2 \cos x)^m$, but when m is not an integer, this is no longer the case, except when x is less than $\pi/2$.

There is no other problem which has occupied mathematicians in recent times as much as this one. Poisson, Poincot, Plana, Crelle and an enormous number of others have tried to solve it, and Poincot is the first to have found the correct sum, but his reasoning is totally false. Until this time no one has been able to get to the end with this [problem]. I am happy that I quite rigorously have arrived to this [end]. A memoir about this will appear in the Journal, and another I will soon send to France to appear in Gergonne's *Annales de Mathematiques*.

[There follows a discussion, omitted here, of some results concerning the above series which Abel has found.]

Divergent series are on the whole devilish, and it is a shame that one dares to base any demonstration on them. One can obtain whatever one wants, when one uses them. It is they which have created so much disaster and so many paradoxes. Can one imagine anything more appalling than to say

$$0 = 1 - 2^n + 3^n - 4^n + \text{etc.}$$

where n is a positive integer? *Risum teneatis amici!*¹

I have in general had my eyes opened in a most astonishing manner: Because when one excludes the most simple cases, for ex. the geometric series, then in the whole of mathematics there is almost no infinite series whose sum is determined in a strict way. In other words, the most important part of mathematics stands there without foundation. Most of it is correct, that is true, which is exceedingly surprising. I am working hard to search for the reason behind this. A very interesting task. I do not think you will be able to propose to me many theorems in which there are infinite series, against whose proof I shall not provide reasoned objections. Do it, and I will answer you.

¹Latin for "Can you keep from laughing, friends!"

[There follows a discussion, omitted here, about the Binomial Series, about which Abel has derived certain results.]

The Taylor theorem, the basis of all of Higher Mathematics, is equally poorly demonstrated. I have found only one strict proof, and that is by Cauchy in his *Leçons sur le calcul infinitésimal*, (of 1823). He there proves that one has:

$$\phi(x + \alpha) = \phi x + \alpha \phi' x + \frac{1}{2} \alpha^2 \phi'' x + \dots$$

as often as the series is convergent (but one uses it easily in all cases). To show by a general example how poorly one is reasoning and how careful one ought to be, I will choose the following example: Let

$$a_0 + a_1 + a_2 + a_3 + a_4 + \text{etc.}$$

be any infinite series. Then you know that a very useful way to sum this series is to search for the sum of the following:

$$a_0 + a_1 x + a_2 x^2 + a_3 x^3 + a_4 x^4 + \text{etc.}$$

and after that to put $x = 1$ in the result. This may be correct, but to me it seems one cannot assume it without proof, because even if one proves that

$$\phi(x) = a_0 + a_1 x + a_2 x^2 + \dots$$

for all values of x less than 1, it cannot be said because of this that the same thing happens for $x = 1$. It could very well be possible that the series $a_0 + a_1 x + a_2 x^2 + \dots$ approaches a quite different quantity than $a_0 + a_1 + a_2 + \dots$ when x approaches more and more to 1. This is clear in the general case when the series $a_0 + a_1 + a_2 + \dots$ is divergent, because then it has no sum. I have proved that it is correct when the series is convergent. The following example shows how one can cheat oneself. It can be strictly proved for all values of x less than π that

$$\frac{x}{2} = \sin x - \frac{1}{2} \sin 2x + \frac{1}{3} \sin 3x - \text{etc.}$$

From this it seems to follow that the same formula should hold for $x = \pi$, but then we would obtain (an absurdity).

.....

One applies all operations to infinite series as if they were finite, but is this permissible? I think not, — Where is it proved that one gets the differential of an infinite series by differentiating each term? It is easy to give an example for which this is not true; e.g.,

$$\frac{x}{2} = \sin x - \frac{1}{2} \sin 2x + \frac{1}{3} \sin 3x - \text{etc.}$$

.....

3 Concluding Questions and Comments

After completing sections 1 and 2 of this project, use the space below to respond to Question 7.

Question 7

What questions or comments do you have about aspects of these extracts that are not addressed in the earlier questions? (Write at least one question and at least one comment, please!)

Instructor Notes

The goal of this Primary Source Project (PSP) is to provide context for the use of rigorous proofs and precise ϵ -inequalities that developed out of concerns about the status of analysis that first arose in the nineteenth century, but which remain defining characteristics of today's analysis. Both these tools of the current trade (i.e., rigorous proof, precise inequalities) offer challenges to students of introductory analysis, who have typically encountered calculus only as a procedural and applied discipline up to this point in their mathematical studies. By offering a glimpse into the problems that motivated nineteenth century mathematicians to shift towards a more formal and abstract study of the concepts underlying these procedures and applications, the readings in this PSP provide students with a context for making a similar shift in their own understanding of these concepts. Completing this PSP early in the course can also provide students and instructors with a basis for reflection on and discussion of current standards of proof and rigor throughout the course.

This version of the PSP is intended to be implemented as follows:

- Students are assigned to read the entire PSP and respond (in writing) to the questions therein prior to class discussion. Typically, the author of the PSP assigns this reading one week prior to a class discussion of it. Students are encouraged to discuss the readings and PSP questions with each other or with the instructor before its due date (provided their written responses are their own). While there is no prohibition against using additional resources to complete the PSP (e.g., a calculus text), it is important to assure students that there is no need to do any historical research in order to complete it.
- On the assignment due date, a whole class discussion (45 - 50 minutes) of the reading is conducted by the instructor, with student responses to various PSP questions elicited during that discussion. An instructor-prepared handout containing solutions to select questions (especially #2) can be helpful during this discussion. The completed written work is collected at the close of that class period (and evaluated for a grade). This discussion could also be conducted after the instructor has collected and read students' written PSP work.

A brief set of summary notes that could be used by an instructor during a whole class discussion of the PSP are included on the subsequent page. Although some type of summarizing discussion is highly recommended, that discussion need not adhere to the notes provided here. LaTeX code for these summary notes, and for the entire PSP, are available from the author upon request; both can be modified by instructors as desired to better suit their course goals.

An alternative version of this PSP is under development that will incorporate the summary ideas presented on the next page as a separate (third) section of the PSP itself. In that alternative version, a whole class discussion of these summary ideas could be completely replaced by student completion of the (new) Section 3 either through individual work outside of class or via small group work during class time. The expected availability date of this alternate version is October 2016.

Acknowledgment

Summary Discussion Notes: *Why be so Critical?*

- Caution that one of the difficulties with historical readings is that the meanings of words change over time; for example, ‘geometer’ referred to any mathematician (not just someone who worked with geometry)
- Overview of pre-nineteenth century calculus themes

Time Period	Focus <i>What objects should we study?</i>	Primary justification of “correctness” <i>How do we know our mathematics is “true”?</i>
17th century	Calculus of CURVES (using algebra as a tool)	New methods produce results that matched “old” (known) results (obtained from geometry)
18th century	Calculus of FUNCTIONS (with physics as primary motivation) NEW QUESTION: What is a function really? Related historical controversies: Fourier Series Convergence Vibrating String Problem	Methods produce correct predictions (in physics) NEW CONCERN: Is it valid to borrow “truths” from one domain (e.g., geometry, physics) to justify truths in another (e.g., mathematics)?

- Status at end of 18th/start of 19th century (*Four main points, I – IV*)
 - Increasing mistrust of “geometric” intuition as valid proof method for “analytic” truths (and more general frustration that analytic “truths” are being verified by non-analytic ‘proofs’)
Ask for evidence of this in the assigned reading.
 - Concern that existing ‘algebraic’ proof methods lack adequate rigor
Ask for evidence of this in the assigned reading; two subthemes to elicit here:
 - Euclid had long been a model of rigor; nineteenth century mathematicians express desire to bring back something like an axiomatic approach as a foundation for certain knowledge
 - algebra allows too much generality (e.g., unrestricted)
Makes it too easy to assume that properties (e.g., continuity, rationality) that hold at all “lower” values will also hold in the limit (*elicit or mention Abel power series example here*)
 - Use of power series (in particular) lacks firm foundation
Ask for evidence of this in the assigned reading; two mathematical points to elicit in particular:
 - Discuss current views about $\sum_{n=1}^{\infty} x^n$ (converges for $-1 < x < 1$ but diverges for $x = \pm 1$)
Discuss Abel’s use of the phrase ‘x less than 1’ here (where today we would write ‘ $|x| < 1$ ’).
 - Abel mentions we could also have convergence for $|x| \leq 1$ with $\lim_{x \rightarrow 1} \phi(x) \neq \phi(1)$.
Ask students for their answers to Question 4 and 5 here.
 - General concerns about foundations: *If we don’t base calculus on power series, what do we use instead?*
 - Some possibilities (and early proponents of each):
Fluxions (Newton) ; Infinitesimals (Leibniz) ; **Limits** (d’Alembert) The “winner”!
 - Chosen option of ‘limit’ raises yet another new question: What is a limit really??
- Ultimate nineteenth century response to this set of concerns:
Require FORMAL PROOFS via RIGOROUS use of INEQUALITIES.
as way to certify knowledge as way to talk about ‘being close’
 - *Historical Aside:* Another factor that influenced this direction were new teaching & research situations (École Polytechnique) that required thinking carefully about ideas in order to explain it to others.
 - This nineteenth century response will be part of the work we do together throughout this course.

An optional historical aside related to item III

The use of power series itself was NOT new in the nineteenth century!

- Power series had been around even before the invention of calculus
- Newton (and others) used power series extensively as infinite polynomials that are easy to integrate, differentiate
- An example from the 17th century: $1 - 1 + 1 - 1 \dots = \frac{1}{2}$

– A first “proof”:

$$(1 - 1) + (1 - 1) + \dots = 0 \quad ; \quad 1 - (1 - 1) + (1 - 1) + \dots = 1$$

Series value is the average: $\frac{0+1}{2} = \frac{1}{2}$.

– A second “proof” (endorsed by Euler, among others):

$$\sum_{n=1}^{\infty} (-1)^n = \frac{1}{1 - (-1)} = \frac{1}{2}$$

For more about this and other divergent series in the 17th century, see the June 2006 MAA On-line column *How Euler Did It* by Ed Sandifer (available at <http://eulerarchive.maa.org/hedi/HEDI-2006-06.pdf>).

An optional historical aside related to nineteenth century mathematicians:

Commenting on his experience following a visit to Paris in 1826, Abel wrote the following to Holmboe:

Legendre is an exceedingly courteous man, but unfortunately as old as the stones.

Cauchy is mad, and you cannot get anywhere with him, although he is the mathematician who knows at the moment how to treat mathematics. Cauchy is extremely Catholic and bigoted. A very strange thing in a mathematician . . .

Poisson is a short man with a nice little belly. He carries himself with dignity. Likewise Fourier. Lacroix is terribly bald and extremely old. On Monday I am going to be introduced to several of these gentlemen by Hachette.

Otherwise I do not like the Frenchman as much as the German, the Frenchman is uncommonly reserved towards foreigners. It is difficult to make his close acquaintance. And I dare not count on such a thing. Everyone wants to teach and nobody to learn. The most absolute egotism prevails everywhere. The only things that the Frenchman seeks from foreigners are the practical. He is the only one who can create something theoretical. You can imagine that it is difficult to become noticed, especially for a beginner.
